

1. What SSIS container allows you to loop through all files in a directory?

That would be the **Foreach Loop Container**. It's the one you use whenever you want to go through a list of files, one after the other.

2. In a Foreach Loop Container, what enumerator type should be selected to loop through file names?

You pick **Foreach File Enumerator**. That tells SSIS you're looping over files, not items in a recordset or something else.

3. How do you make the Flat File Connection dynamic inside a Foreach Loop?

You set the **ConnectionString property** of the Flat File Connection Manager to use a variable. Then, in the loop, you map the current file name to that variable. This way, each time the loop runs, the connection points to the right file.

4. What is the purpose of setting DelayValidation = True in a Data Flow Task?

It tells SSIS: "Don't validate this task right now." This is useful when the file or table doesn't exist yet at design time but will exist at runtime. It basically prevents errors from popping up too early.

5. In C#, how do you exclude the header row (first line) from a file being processed?

The usual way is to read the first line and ignore it before starting your loop. For example:

6. How can you filter only .txt files using Foreach Loop?

In the Foreach Loop Editor, you can set the file mask to *.txt. That way, SSIS only picks up text files and ignores everything else.

7. Describe how to insert data into SQL Server using a Script Task with dynamically generated INSERT statements.

Inside the Script Task, you can build an INSERT INTO ... VALUES ... string based on the data you're reading. Then you run it with a SqlCommand against your database connection. For example, loop through each line, create the insert SQL, and execute it.

8. How can you display the full file path for each file inside a Script Task?

Just pass the file name variable from the Foreach Loop into the Script Task. Inside the script, you can do:

```
MessageBox.Show(Dts.Variables["User::FileName"].Value.ToString());
```

Or log it using `Dts.Events.FireInformation`.

9. What changes are needed in a Flat File Connection Manager to allow importing a different file every loop?

You have to set the **ConnectionString** property to be driven by a variable instead of a fixed path. That way, when the Foreach Loop updates the variable with the current file, the Flat File Connection Manager automatically points to that file.
